**THE DISTRIBUTION OF *CORYDALUS CORNUTUS* (LINNAEUS)  
AND *NIGRONIA SERRICORNIS* (SAY) (MEGALOPTERA:  
CORYDALIDAE) IN MICHIGAN**

Allen W. Knight and Clifford A. Siegfried<sup>1</sup>

INTRODUCTION

The distribution of the hellgrammite [*Corydalus cornutus* (Linnaeus)] and the sawcombed fishfly [*Nigronia serricornis* (Say)] in Michigan was determined as part of an investigation of the biology of these large Megalopterans (Knight and Simmons, 1975a, 1975b). Megalopteran larvae are some of the largest aquatic insects, with a maximum length of approximately 84 mm. They are robust larvae with paired lateral abdominal appendages on segments 1-8 and a pair of anal prolegs bearing two strong hooks. They are fiercely predaceous and generally insectivorous, feeding chiefly on larvae of *Simulium*, *Cheumatopsyche*, *Hydropsyche* and *Chironomidae*, but eating almost anything they can subdue, including their own kind (Chandler, 1956; Stewart *et al.*, 1973).

The Corydalidae genera of Michigan are easily separated as larvae and adults. The adult of *Corydalus* is easily recognized by large mandibles protruding beyond the labrum, especially prominent in males. The larvae of *Corydalus* are separated from those of other corydalids by the large tufts of filamentous gills at the base of each lateral process. The adults of *Nigronia* and *Chauliodes* (*Chauliodes* was not included in the present study) can be separated by coloration (*Nigronia* being black and *Chauliodes* gray and mottled) as well as wing venation and the shape of the ocellus (Chandler, 1956). *Chauliodes* larvae are distinguished by long respiratory tubes extending from the eighth abdominal segment well past the end of the terminal claws. *Nigronia* has much shorter respiratory tubes, generally only about 1½ times as long as wide.

To date, information on the distribution or biology of Corydalidae in Michigan is only fragmentary (Hazard, 1969; Petersen, 1974). Distribution data for aquatic insects such as the Corydalidae can be important historically since they provide an indication of the water quality at the time of the survey. Changes in distribution patterns are often associated with changes in water quality. Conversely, distribution data can provide information on the habitat requirements of aquatic insects.

The distributions reported below are based on an extensive survey of accessible streams of Michigan, carried out from June, 1966, to July, 1969, and an examination of collections at the University of Michigan and at Michigan State University.

RESULTS

*Nigronia serricornis* (Say)

*N. serricornis* is generally distributed throughout Michigan (Fig. 1) except in the heavily industrialized counties of central and southeast Michigan, and Berrien County in the southwest. *N. serricornis* was also not collected in three counties of the Upper Peninsula. These include Keweenaw and Houghton Counties, the streams of which often contain copper from copper mining, and Chippewa County, which has little running water so few sites were sampled in the present survey.

Although Chandler (1956) states that *Nigronia* is found in quiet or stagnant water, our results demonstrate its widespread occurrence in the lotic waters of Michigan. *N.*

<sup>1</sup>Hydrobiology Laboratory, Department of Land, Air and Water Resources, Water Science and Engineering Section, University of California, Davis, California 95616.

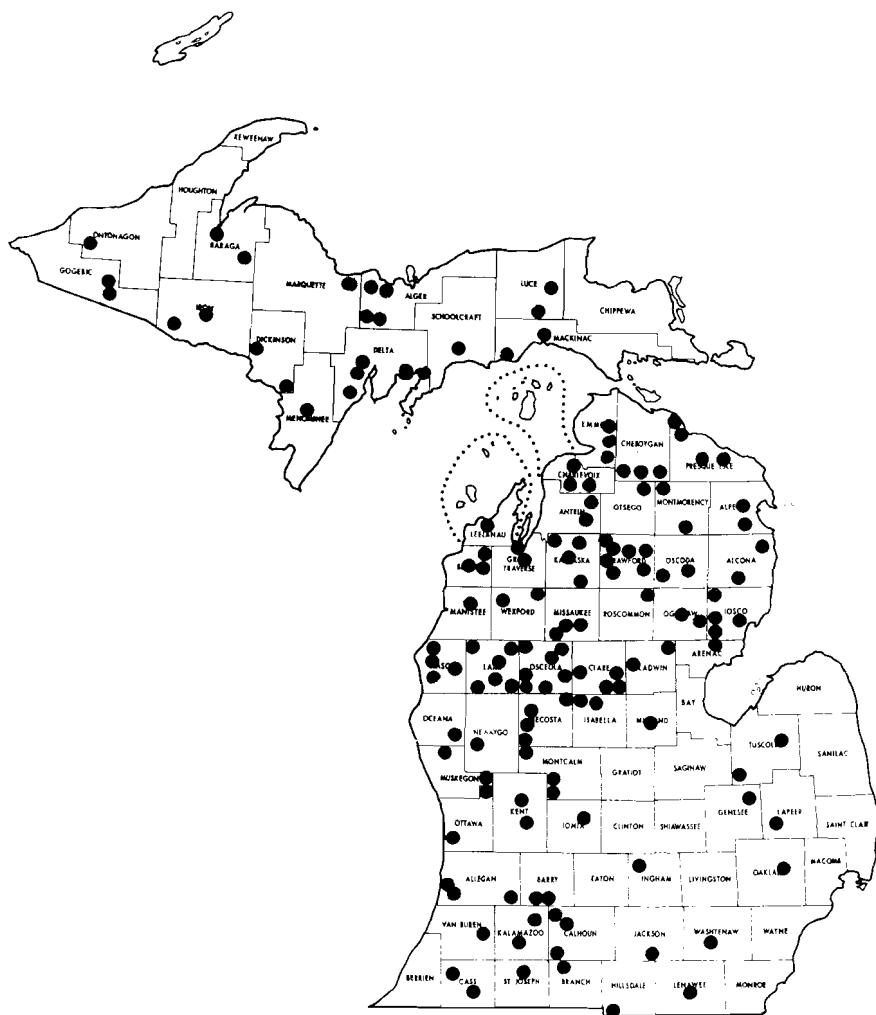

Fig. 1. The distribution of *Nigronia serricornis* (Say) in Michigan, June, 1966, to July, 1969.

*serricornis* larvae appeared flexible in habitat requirements, being found on substrates ranging from sand and mud to boulders with frequent branches and logs which are apparently a preferred habitat for *Nigronia*.

#### *Corydalus cornutus* (Linnaeus)

*C. cornutus* is restricted to the south half of the Lower Peninsula (Fig. 2). It is generally distributed in the south, although absent from the heavily industrialized counties of central and southeast Michigan.

Fig. 2. The distribution of *Corydalus cornutus* (L.) in Michigan, June, 1966, to July, 1969.

*C. cornutus* larvae were generally collected from cobble-boulder substrata. They were especially abundant below dams, preying on abundant simulid larvae and other filter feeding organisms.

The absence of *Nigronia* and *Corydalus* larvae from the streams of central and southeast Michigan may reflect their sensitivity to urbanization. *Corydalus* may be slightly more tolerant of the effects of urbanization than is *Nigronia*.

*Nigronia* and *Corydalus* were found to be sympatric in only nine of a possible 185 instances in which they were found. *C. cornutus* appears to be excluded from the

northern portion of the Lower Peninsula and from the entire Upper Peninsula. Inter-specific competition with *N. serricornis* may be responsible for the restriction of *C. cornutus* to southern Michigan. In southern Michigan the streams are generally summer-warm, often exceeding 30°C. Knight and Simmons (1975a) have demonstrated that larvae of *C. cornutus* have a respiratory adaptation to increasing temperature that is lacking in *N. serricornis* (Knight and Simmons, 1975b). This may allow *C. cornutus* to compete with *N. serricornis* in the southern summer-warm streams but offers no advantage in the summer-cool streams of northern Michigan with maximum temperature generally less than 28°C. It is also possible that the differences in distribution reflect basic differences in environmental preference or tolerance. The streams of southern Michigan are generally broader and have lower gradients than those of northern Michigan. Concentrations of dissolved solids, hardness, chloride and sulfate increase from north to south in Michigan streams (Wood, 1970) and may influence the distribution of *Corydalus* and *Nigronia*. More detailed studies are necessary to determine the mechanisms operating to determine the distribution of these two corydalids.

Collection records (All collections without collector's name are from the present survey; sex indications following collectors' names are for adult specimens only):

*Nigronia serricornis*

#### ACKNOWLEDGMENTS

This investigation was supported in part by the Federal Water Pollution Control Administration, Research Grant No. WP-01178-01. Financial support to the senior author by Michigan State University and the University of California Agricultural Experiment Station aided in data collection, processing, and manuscript preparation. The authors are grateful to Dr. Dennis Heiman, Mr. Warren Alward, and Mr. Mike Petitpren for their field and laboratory assistance.
