AN ANNOTATED CHECKLIST OF THE LEPIDOPTERA OF THE BEAVER ISLAND ARCHIPELAGO, LAKE MICHIGAN.

Dennis Profant¹

ABSTRACT

A survey of Lepidoptera was conducted in 1987 and 1988 on Beaver Island, Lake Michigan. When combined with a 1930 survey of the Beaver Island Archipelago, 757 species from 41 families have now been recorded from these islands.

Only one study has been published on the Lepidoptera of Beaver Island and the surrounding islands of Garden, High, Hog, Whiskey, Squaw, Trout, Gull, and Hat (Moore 1930). The present study has produced a more complete inventory of lepidopteran species on Beaver Island. Collecting was done in a variety of habitats using several different light sources. Emphasis was placed on the Microlepidoptera which were largely omitted in the original work by Moore (1930).

Beaver Island is the largest of a group of nine named islands located in the extreme northeastern portion of Lake Michigan, (Fig. 1). Situated 51 km northwest of Charlevoix, Michigan, the island is 20 km long by 11 km wide and consists of several hundred permanent residents who reside primarily in the town of St. James. The island has a maritime climate and frosts can occur well into May and again in September. While the summer air is usually hot during the day, 26°C, it often is very cool at night. 10°C is not unusual in June, July, and August, (Jacque LaFreniere, pers. comm.).

The northern part of the island is underlain with limestone formations which form outcrops in various places. The interior is gently rolling, corresponding to the original glacial drift. Behind the shoreline are a series of sand dunes and terraces, the largest of which occurs on the west side of the island. The highest point in this dune complex is approximately 61 m high (Darlington 1940). It is probable that the Beaver archipelago has not been connected to the mainland since the last glacial epoch. The fauna must have crossed the water after the retreat of the Wisconsin ice sheet some 15,000 years ago. The water would be only a slight barrier for winged insects, especially Lepidoptera. The species found on the island have a marked northern affinity and may have been carried from the Upper Peninsula by the frequent strong northwest winds (Moore 1930).

Beaver Island occurs in the hemlock-white pine-northern hardwoods forest region (Braun 1950). The beaches and dunes consist of vegetation characteristic of this latitude. Much of the island perimeter consists of coniferous forests (mixed fir, spruce, cedar, hemlock, and pine). A number of inland lakes contain sphagnum bogs or bog forests. Years ago the island residents put much of the land into cultivation and many of these farmlands have reverted to old fields and second growth forests of paper birch (*Betula papyrifera*) and a bracken fern (*Pteridium aquilinum*) understory.

Figure 1. Location of the Beaver Island Archipelago.

MATERIALS AND METHODS

Lepidoptera were collected between July and September 1987, and periodically between May and August 1988. A few records were obtained from a small teaching collection at the Central Michigan University (CMU) Biological Station. Most species in table 1 without collecting dates came from this collection. White sheets illuminated by a 200 watt incandescent light bulb and/or several filtered black lights (BLB) were used for night collecting. Buildings with mercury vapor lights were also utilized. Sugaring for moths with a beer-molasses bait proved unproductive. Moths were collected 4-5 times a week and at all hours of the night.

Habitats sampled on the island included hemlock woods, beech-maple forest, sphagnum bog, cedar woods, northern hardwoods, coniferous forest, lake edges, marshes, and open fields. The primary collection sites responsible for the largest percentage of species collected were the CMU Biological Station and campground.

The beach and dunes at the station were typified by *Prunus pennsylvanica*, *Populus balsamifera*, *Salix cordata*, *Potentilla fruticosa*, *Juniper spp.*, *Arctostaphylos uva-ursi*, *Campanula rotundifolia*, *Lithospermum carolinense*, and *Zigadenus glaucus*. Behind the dunes was an area dominated by *Pinus resinosa*, and *P. strobus*, with an understory of bracken fern, *Smilacina stellata*, *Linnaea borealis*, and *Silene vulgaris*. The campground was a mixed hardwood-coniferous community. Common plants included paper birch, *Tsuga canadensis*, *Thuja occidentalis*, *Populus tremuloides*, *Abies balsamea*, *Picea glauca*, *Ostrya virginiana*, *Betula alleghaniensis*, *Cornus canadensis*, *Clintonia borealis*, *Maianthemum canadense*, and *Polygala paucifolia*.

Collected specimens remain in the personal collection of the author. Identifications were made using a comparative collection at Michigan State University. Taxonomic literature used for identification included the following: Covell (1984), Forbes (1923, 1948), Hodges et al. (1974, 1986), Howe (1975), Klots (1951), LaFontaine et al. (1987), McGuffin (1972, 1977, 1981, 1987), Miller (1987), Rockburne & LaFontaine (1976), and Sargent (1976). Phylogenetic arrangement and nomenclature followed that of Hodges et al. (1983). Genera or species followed by a question mark in the checklist indicate unsure identifications.

RESULTS

A total of 757 lepidopteran species from 41 families has now been recorded from the Beaver Island archipelago. 701 of these species were from Beaver Island; 517 species were collected in this study and 184 additional species were reported by Moore (1930). Approximately 35 species of microlepidoptera remain unidentified. Table 1 lists all identified species collected from the Beaver Island archipelago. Species not collected on Beaver Island are listed with the island on which they were originally recorded by Moore (1930).

DISCUSSION

Moore (1930) listed *Gluphisia lintneri* (Notodontidae) as occurring on Beaver Island. Originally *G. lintneri* and *G. avimacula* were synonymous and therefore mixed in Moore's data. The two are now valid species and *G. avimacula* is extremely abundant on Beaver Island. Although *G. lintneri* may occur, none were collected, and upon examination of Moore's specimens at the University of Michigan collection, all were *G. avimacula*. *Enargia decolor* (Noctuidae) and *E. infumata*, were also originally thought to be one species. Although Moore (1930) listed only *E. decolor*, his specimens include data on both species. Another noctuid, listed by Moore (1930) as *Euplexia lucipara* is now referred to as *E. benesimilis* (Hodges et al. 1983). *E. lucipara* is a palearctic species and does not occur in North America. No endangered or threatened species were found based on the list of endangered lepidopteran species of Michigan (DNR 1988). One "species of special concern" (DNR 1988), *Papaipema aweme* (one specimen), (Noctuidae), was recorded by Moore (1930). This species is known only from a few specimens collected in various parts of North America (M. C. Nielsen, pers. comm.). Little is known about its life history, but the

species may be associated with wetlands or shoreline environments. Repeated efforts to recollect it along lake edges were unsuccessful.

Further investigations should turn up additional species new to Beaver Island, especially moths at ultraviolet/mercury vapor lights. Future collecting should be concentrated in the southern portions of the island and in a variety of habitats. With the exception of Iron Ore Bay, collecting has been virtually nonexistent in areas surrounding Green's Bay, French Bay, Miller's Marsh, Lake Geneserath, and on the satellite islands.

ACKNOWLEDGMENTS

I thank J. Gillingham, Central Michigan University (CMU) Biological Station, for his cooperation in collecting at the station, and R. G. Bland, CMU, for reviewing the manuscript and being advisor on this project. R. L. Fischer, Michigan State University and M. F. O'Brien, University of Michigan Museum of Zoology, allowed access to the university insect collections. M. C. Nielsen, Lansing, provided valuable assistance in identification.
